

HEIDENHAIN

Modular Magnetic Encoders

September 2012

The ERM modular encoders from HEIDENHAIN consist of a magnetized scale drum and a scanning unit with magnetoresistive sensor. Their MAGNODUR measuring standard and the magnetoresistive scanning principle make them particularly tolerant to contamination.

Typical applications, usually with reduced accuracy requirements, include machines and equipment with **large hollow shaft diameters** in environments with large amounts of airborne particles and liquids, for example on the spindles of lathes or milling machines.

Information on

ERM 2400

ERM 2900

Applications

Requirements on productivity and machining quality are steadily increasing. The complexity of workpieces and changing operating conditions due to small batch sizes in part manufacturing are likewise increasing. This must be considered in a production machine's conception and mechanical design in order for such machines to work highly efficiently and precisely.

The robust ERM modular magnetic encoders are especially suited for use in production machines. Their large inside diameters offered, their small dimensions and the compact design of the scanning head predestine them for

- the C axis of lathes,
- rotary and tilting axes (e.g. for speed measurement on direct drives or for integration in gear stages), and
- spindle orientation on milling machines or auxiliary axes.

C axis on lathes

Typical requirements:

- Various hollow-shaft diameters
- Resistant to contamination
- Simple installation

Suitable encoder

- ERM 200 series
- Possibly the ERM 2200 series

For years, the ERMs have been the preferred encoders for C axes on lathes. Besides their high resistance to contamination, the large inside diameters are also important to allow bar material to be machined without limitations.

Because of this design arrangement, the graduation of the ERM is usually on a much larger diameter than the workpiece. Position errors of the encoder therefore affect workpiece accuracy to a correspondingly reduced degree.

For example, the position error within one signal period, which is approx. $2 \mu\text{m}$ on a scale drum with 2048 lines and a diameter of 257.5 mm, engenders positioning error of only $0.8 \mu\text{m}$ on a workpiece with diameter 100 mm. A smaller workpiece diameter will have an even better value.

The accuracy and reproducibility of the ERM therefore also achieve workpiece accuracy values sufficient for milling operations with lathes (classic C-axis machining).

Rotary and tilting tables

Typical requirements:

- Medium to high accuracy
- Large hollow-shaft diameter
- Resistant to contamination

Suitable encoder

- ERM 2200 series

Rotary tables and tilting axes require encoders with high signal quality for position and speed control. Encoders with optical measuring standards, for example the RCN series, fulfill these requirements in an ideal way. For medium accuracy requirements magnetic modular encoders can also be used. Due to their small signal period of 200 μm , the ERM 2200 encoders feature particularly low position error within one signal period and therefore permit relatively high axis speed stability. In addition, the typical advantages of magnetic modular encoders, such as tolerance to contamination and large inside diameters, are very helpful in this application.

Spindles on milling machines

Typical requirements:

- High shaft speeds
- Small mounting space

Suitable encoder

- ERM 2400 series
- ERM 2900 series

Spindles are among the key components of machine tools and significantly influence their function. The spindle properties are determined by design, drives and bearing systems, but also the encoders make a decisive contribution to performance. They have to permit high rotational speeds and be sufficiently sturdy. Speeds of over 40000 rpm are no problem for the ERM 2900. In addition they fulfill the requirement for compact dimensions.

If milling and turning operations are to be performed on one machine, increased requirements for spindle accuracy are the result. On complex workpieces, certain machining movements can be performed only through the interaction of feed axes and spindle positions. For example, when manufacturing a thread, a single-point tool needs to assume a defined angular attitude. Here the ERM 2400 encoders with 400 μm signal period come into use. They have better accuracy behavior and, for example, 600 lines on an outside diameter of 75.44 mm. This is significantly more than gears with comparable dimensions.

Properties

The ERM magnetic modular encoders from HEIDENHAIN are characterized by the following properties:

Insensitive to contamination

The encoder in the machine tool is often exposed to heavy loads from cooling lubricants. Particularly with high spindle speeds and large diameters, sealing it becomes very difficult. Here the ERM magnetic modular encoders with their high resistance to contamination are of particular benefit: they can even operate under high humidity, heavy dust loads, and in oily atmospheres.

Large hollow shafts in small installation space

ERM encoders are characterized by compact dimensions and large inside diameters of up to 410 mm. Larger diameters are available upon request.

Simple mounting

Mounting the scale drum and scanning head is decidedly simple and requires little adjustment. The scale drum is centered via the centering collar on its inner circumference. The scanning head is easily positioned with respect to the scale drum by means of a spacer foil. If the recommended mounting tolerances are complied with, it is not necessary to inspect the output signals or readjust them.

High shaft speeds

The scale drums were specially conceived for high shaft speeds. The maximum permissible speeds shown in the specifications also apply for extreme loads. This allows continuous operation at the maximum permissible speed as well as the more demanding reciprocating traverse. Even reciprocating traverse with ongoing braking and acceleration processes, even with direction reversal, can be performed at the maximum permissible speeds. The reciprocation is based on 10 million load reversals and therefore fulfills the requirements for fatigue strength.

The ERM is completely quiet in operation, even at maximum speeds. Ancillary noises, such as from gear-tooth systems, do not occur.

High signal quality

The output signals of the ERM magnetic modular encoders are characterized by high signal quality: Together with the signal period, signal quality is decisive for position error within one signal period. With the magnetic modular encoders, as with many other HEIDENHAIN encoders, this value is significantly better than 1% of the signal period. For the ERM 2200 and ERM 200 series, the position error within one signal period is typically less than 0.5% of the signal period.

Purely serial interface

Besides the incremental output signals, it is possible to transmit the position information as position values over the EnDat 2.2 interface. The sinusoidal scanning signals are highly interpolated in the scanning head and converted to a position value by the integrated counter function. As with all incremental encoders, the absolute reference is determined with the aid of reference marks. A scale drum with distance-coded reference marks is required on these encoders in order to facilitate "homing" the encoder.

The EnDat 2.2 interface offers a large number of other benefits besides serial transmission of the position value, such as automatic self-configuration, monitoring and diagnostic functions, and high reliability of data transmission.

Screen showing the valuation numbers as functional reserves (e.g. with ATS software)

ERM scale drums

Measuring principle

Measuring standard

HEIDENHAIN encoders incorporate measuring standards of periodic structures known as graduations.

Magnetic encoders use a graduation carrier of magnetizable steel alloy. A write head applies strong local magnetic fields in different directions to form a graduation consisting of north poles and south poles (MAGNODUR process).

The following grating periods are possible on the circumference:

- Approx. 200 μm for ERM 2200
- Approx. 400 μm for ERM 200, ERM 2400, ERM 2410
- Approx. 1000 μm for ERM 2900

Due to the short distance of effect of electromagnetic interaction and the very narrow scanning gaps required, finer magnetic graduations have significantly tighter mounting tolerances.

Magnetic scanning

The permanently magnetic MAGNODUR graduation is scanned by magnetoresistive sensors. They consist of resistive tracks whose resistance changes in response to a magnetic field. When a voltage is applied to the sensor and the scale drum moves relative to the scanning head, the flowing current is modulated according to the magnetic field.

The special geometric arrangement of the resistive sensors and the manufacture of the sensors on glass substrates ensure a high signal quality. In addition, the large scanning surface allows the signals to be filtered for harmonic waves. These are prerequisites for minimizing position errors within one signal period.

A magnetic structure on a separate track produces a reference mark signal. This makes it possible to assign this absolute position value to exactly one measuring step.

Magnetoresistive scanning is typically used for medium-accuracy applications, or for where the diameter of the machined part is relatively small compared to the scale drum.

Incremental measuring method

With the incremental measuring method, the graduation consists of a periodic grating structure. The position information is obtained **by counting** the individual increments (measuring steps) from some point of origin. The shaft speed is determined through mathematical derivation of the change in position over time.

Since an absolute reference is required to ascertain positions, the scale drums are provided with an additional track that bears a **reference mark** or multiple reference marks. The absolute position on the scale, established by the reference mark, is gated with exactly one measuring step. The reference mark must therefore be scanned to establish an absolute reference or to find the last selected datum. The scale drums of the ERM 2200 and ERM 2410 feature distance-coded reference marks. Here the absolute reference is established by scanning two neighboring reference marks (see *Angle for absolute reference* in the Specifications).

Magnetoresistive scanning principle

Measuring accuracy

The accuracy of angular measurement is mainly determined by

- the quality of the graduation,
- the stability of the graduation carrier,
- the quality of the scanning process,
- the quality of the signal processing electronics,
- the eccentricity of the graduation to the bearing,
- the error of the bearing, and
- the coupling to the measured shaft.

These factors of influence are comprised of encoder-specific error and application-dependent issues. All individual factors of influence must be considered in order to assess the attainable total accuracy.

Encoder-specific error

The encoder-specific error is given in the Specifications:

- Accuracy of graduation
- Position error within one signal period

Accuracy of graduation

The accuracy of the graduation $\pm a$ results from its quality. This includes

- the homogeneity and period definition of the graduation,
- the alignment of the graduation on its carrier, and
- the stability of the graduation carrier, in order to also ensure accuracy in the mounted condition.

The accuracy of the graduation $\pm a$ is ascertained under ideal conditions by using a series-produced scanning head to measure position error at positions that are integral multiples of the signal period.

Position error within one signal period

The position error within one signal period $\pm u$ results from the quality of the scanning and—for encoders with integrated pulse-shaping or counter electronics—the quality of the signal-processing electronics. For encoders with sinusoidal output signals, however, the error of signal processing is influenced by the subsequent electronics.

The following individual factors influence the result:

- The size of the signal period
- The homogeneity and period definition of the graduation
- The quality of scanning filter structures
- The characteristics of the detectors
- The stability and dynamics of further processing of the analog signals

These factors of influence are to be considered when specifying position error within one signal period.

Position error within one signal period $\pm u$ is specified in percent of the signal period. For the ERM magnetic modular encoders with approx. 200 μm or 400 μm , the value is typically better than $\pm 0.5\%$ of the signal period. You will find the values in the Specifications.

Position errors within one signal period already become apparent in very small angular motions and in repeated measurements. They especially lead to speed ripples in the speed control loop.

Application-dependent error

The mounting and adjustment of the scanning head drum, in addition to the given encoder-specific error, normally have a significant effect on the accuracy that can be achieved by **encoders without integral bearings**. Of particular importance are the mounting eccentricity of the graduation and the radial runout of the measured shaft. The application-dependent error values must be measured and calculated individually in order to evaluate the total accuracy.

On the other hand, the specified system accuracy for the encoders with integral bearing already includes the error of the bearing and the shaft coupling. (See the *Absolute Angle Encoders with Optimized Scanning* or *Angle Encoders with Integral Bearing* brochures.)

Errors due to eccentricity of the graduation to the bearing

Under normal circumstances, the graduation will have a certain eccentricity relative to the bearing once the ERM's scale drum is mounted. In addition, dimensional and form deviations of the customer's shaft can result in added eccentricity. The following relationship exists between the eccentricity e , the graduation diameter D and the measuring error $\Delta\varphi$ (see illustration below):

$$\Delta\varphi = \pm 412 \cdot \frac{e}{D}$$

$\Delta\varphi$ = Measuring error in " (angular seconds)

e = Eccentricity of the scale drum to the bearing in μm (1/2 the radial deviation)

D = Scale-drum diameter (= drum outside diameter) in mm

M = Center of graduation

φ = "True" angle

φ' = Scanned angle

Error due to radial runout of the bearing

The equation for the measuring error $\Delta\varphi$ is also valid for radial deviation of the bearing if the value e is replaced with the eccentricity value, i.e. half of the radial deviation (half of the displayed value). Bearing compliance to radial shaft loading causes similar errors.

Deformation of the graduation

Error due to deformation of the graduation is not to be ignored. It occurs when the graduation is mounted on an uneven, for example convex, surface.

However, the graduation can also be deformed solely by screw tightening torque. The scale drums of the ERM 2200, ERM 200 and ERM 2410 are particularly rigid in order to prevent this effect.

Eccentricity of the graduation to the bearing

Resultant measured deviations $\Delta\varphi$ for various eccentricity values e as a function of graduation diameter D

Mechanical design types and mounting

The ERM modular encoders consist of a circumferential scale drum and the corresponding scanning head. The assemblies of the scanning head and graduation relative to each other is determined solely via the machine bearing. However, special design features of the ERM modular encoders assure comparably fast mounting and easy adjustment. The data for graduation accuracy and the position error within one signal period can be attained in the application if the requirements are fulfilled (see *Specifications*).

Versions

There are various signal periods available for the ERM modular magnetic encoders (ERM 2200: approx. 200 µm, ERM 200/2400: approx. 400 µm, ERM 2900: approx. 1 mm). This results in different line counts for the same outside diameter.

The scale drums are available in three versions. They differ essentially in the type of mounting. All scale drums feature a centering collar on the inside diameter.

TTR ERM 2200 and TTR ERM 200 scale drums

For mounting, the scale drums are slid onto the mating shaft and fastened axially with screws.

TTR ERM 2x0x scale drum

The **TTR ERM 2404**, **TTR ERM 2405** and **TTR ERM 2904** scale drums are fastened only by a friction-locked connection to the mating surface. The clamping of the scale drum depends on the mounting situation. The clamping force must be applied evenly over the plane surface of the drum. The necessary mounting elements depend on the design of the customer's equipment, and are therefore the responsibility of the customer. The frictional connection must be strong enough to prevent unintentional rotation or skewing in axial and radial directions, even at high speeds and accelerations. The scale drum must not be modified for this purpose, such as by drilling holes or countersinks in it.

The **TTR ERM 2404** and **TTR ERM 2904** versions feature a smooth inside drum surface. Only a friction-locked connection

(clamping of the drum) is to be used to prevent them from rotating unintentionally. The **TTR ERM 2405** scale drums feature a keyway. The feather key is intended only for the prevention of unintentional rotation and not for the transmission of torque. The special shape of the drum's inside ensures stability even at the maximum permissible speeds.

Centering the scale drum

Because the attainable total accuracy is dominated by mounting error (mainly through eccentricity), special attention must be placed on centering the scale drum. Depending on the encoder and mounting method, various methods of centering the scale drums are possible in order to minimize the eccentricity errors that occur in practice.

1. Centering by centering collar

The scale drum is pushed or shrunk onto the shaft. This very simple method requires an exact shaft geometry and bearing quality to meet the corresponding accuracy requirements.

Mounting of the scale drum
TTR ERM 200
TTR ERM 2200

Mounting of the scale drum
TTR ERM 2404
TTR ERM 2904

Mounting of the scale drum
TTR ERM 2405

The scale drum is centered via the centering collar on its inner circumference. HEIDENHAIN recommends a slight oversize of the shaft on which the scale drum is to be mounted. For easier mounting, the scale drum may be slowly warmed on a heating plate over a period of approx. 10 minutes to a temperature of at most 100 °C. In order to check the radial runout and assess the resulting deviations, testing of the rotational accuracy before mounting is recommended.

Back-off threads are used for dismounting the scale drums.

2. Centering with two scanning heads

This method is suited for scale drums with screw fastening. Here the graduation or the position value itself serves as reference. The two scanning heads are connected with the subsequent electronics, which form the difference of the two position values. This centering method is recommended when high accuracy is required or when error caused by the shaft geometry or the bearing is to be avoided.

Mounting the scanning head

In order to mount the scanning head, the spacer foil is applied to the surface of the circumferential scale drum. The scanning head is pressed against the foil and fastened. The foil is then removed.

Test film for magnetic graduation

The test film is used to make the magnetic graduation visible. It enables the user to easily check whether there is any damage to the magnetic graduation, such as demagnetization from a tool. The test film can be "cleaned" with the aid of a demagnetization device and therefore used repeatedly. The test film and demagnetization device are available as accessories.

Mounting clearance

The mounting clearance (gap between scanning head and scale drum) depends on the encoder's signal period. As a result, the spacer foils for mounting the scanning head are of varying thicknesses. Deviations of the scale-to-reticle gap from the ideal value negatively influence the signal amplitude.

Measuring with two scanning heads

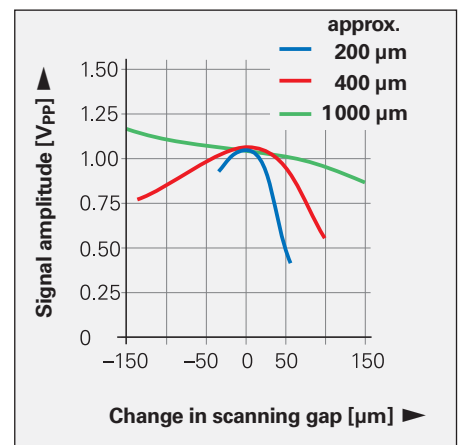

Error caused by the eccentricity of the graduation to the bearing are compensated with the aid of a second scanning head that is arranged at an angle of $180^\circ \pm 5^\circ$ to the first one. The incremental signals of both scanning heads are digitally offset in an external EIB 1500 interface box with a high subdivision factor and are transmitted as absolute position values after the reference mark is scanned. (See Product Information *EIB 1500*).

General mechanical information

Protection against contact

After encoder installation, all rotating parts must be protected against accidental contact during operation.

Acceleration

Encoders are subject to various types of acceleration during operation and mounting.

- The indicated maximum values for **vibration** are valid according to EN 60068-2-6.
- The maximum permissible acceleration values (semi-sinusoidal shock) for **shock and impact** are valid for 6 ms (EN 60068-2-27).

Under no circumstances should a hammer or similar implement be used to adjust or position the encoder.

Temperature range

The **operating temperature range** indicates the ambient temperature limits between which the encoders will function properly.

The **storage temperature range** from -30 °C to $+70\text{ °C}$ is valid as long as the unit remains in its packaging.

Rotational velocity

The maximum permissible shaft speeds were determined according to FKM guidelines. This guideline serves as mathematical attestation of component strength with regard to all relevant influences and it reflects the latest state of the art. The requirements for fatigue strength (10 million reversals of load) were considered in the calculation of the permissible shaft speeds. Because installation has significant influence, all requirements and directions in the specifications and mounting instructions must be followed for the rotational velocity data to be valid.

Expendable parts

HEIDENHAIN encoders contain components that are subject to wear, depending on the application and handling. These include in particular moving cables. Pay attention to the minimum permissible bending radii.

Mounting

Work steps to be performed and dimensions to be maintained during mounting are specified solely in the mounting instructions supplied with the unit. All data in this catalog regarding mounting are therefore provisional and not binding; they do not become terms of a contract.

System tests

Encoders from HEIDENHAIN are usually integrated as components in larger systems. Such applications require **comprehensive tests of the entire system** regardless of the specifications of the encoder.

The specifications shown in this brochure apply to the specific encoder, not to the complete system. Any operation of the encoder outside of the specified range or for any other than the intended applications is at the user's own risk.

In safety-related systems, the higher-level system must verify the position value of the encoder after switch-on.

Interfaces

Incremental signals $\sim 1 V_{PP}$

HEIDENHAIN encoders with $\sim 1 V_{PP}$ interface provide voltage signals that can be highly interpolated.

The sinusoidal **incremental signals** A and B are phase-shifted by 90° elec. and have an amplitude of typically $1 V_{PP}$. The illustrated sequence of output signals—with B lagging A—applies for the direction of motion shown in the dimension drawing.

The **reference mark signal** R has a usable component G of approx. $0.5 V$. Next to the reference mark, the output signal can be reduced by up to $1.7 V$ to a quiescent level H. This must not cause the subsequent electronics to overdrive. Even at the lowered signal level, signal peaks with the amplitude G can also appear.

The data on **signal amplitude** apply when the power supply given in the specifications is connected to the encoder. They refer to a differential measurement at the 120 ohm terminating resistor between the associated outputs. The signal amplitude decreases with increasing frequency. The **cutoff frequency** indicates the scanning frequency at which a certain percentage of the original signal amplitude is maintained:

- $-3 \text{ dB} \triangleq 70 \%$ of the signal amplitude
- $-6 \text{ dB} \triangleq 50 \%$ of the signal amplitude

The data in the signal description apply to motions at up to 20% of the -3 dB cutoff frequency.

Interpolation/resolution/measuring step

The output signals of the $1 V_{PP}$ interface are usually interpolated in the subsequent electronics in order to attain sufficiently high resolutions. For **velocity control**, interpolation factors are commonly over 1000 in order to receive usable information even at low rotational or linear velocities.

Measuring steps for **position measurement** are recommended in the specifications. For special applications, other resolutions are also possible.

Short-circuit stability

A temporary short circuit of one signal output to $0 V$ or U_P (except encoders with $U_{Pmin} = 3.6 V$) does not cause encoder failure, but it is not a permissible operating condition.

Short circuit at	20 °C	125 °C

Connecting cable	Shielded HEIDENHAIN cable For example PUR $[4(2 \times 0.14 \text{ mm}^2) + (4 \times 0.5 \text{ mm}^2)]$ Max. 150 m at 90 pF/m distributed capacitance 6 ns/m
Cable length	
Propagation time	

These values can be used for dimensioning of the subsequent electronics. Any limited tolerances in the encoders are listed in the specifications. For encoders without integral bearing, reduced tolerances are recommended for initial operation (see the mounting instructions).

Cutoff frequency

Typical signal amplitude curve with respect to the scanning frequency (depends on encoder)

Input circuitry of subsequent electronics

Dimensioning

Operational amplifier MC 34074

$Z_0 = 120 \Omega$

$R_1 = 10 \text{ k}\Omega$ and $C_1 = 100 \text{ pF}$

$R_2 = 34.8 \text{ k}\Omega$ and $C_2 = 10 \text{ pF}$

$U_B = \pm 15 \text{ V}$

U_1 approx. U_0

-3 dB cutoff frequency of circuitry

Approx. 450 kHz

Approx. 50 kHz with $C_1 = 1000 \text{ pF}$
and $C_2 = 82 \text{ pF}$

The circuit variant for 50 kHz does reduce the bandwidth of the circuit, but in doing so it improves its noise immunity.

Encoders with **higher signal frequencies** (e.g. LIP 281) require special input circuitry (see the *Exposed Linear Encoders* brochure).

Circuit output signals

$U_a = 3.48 V_{PP}$ typically

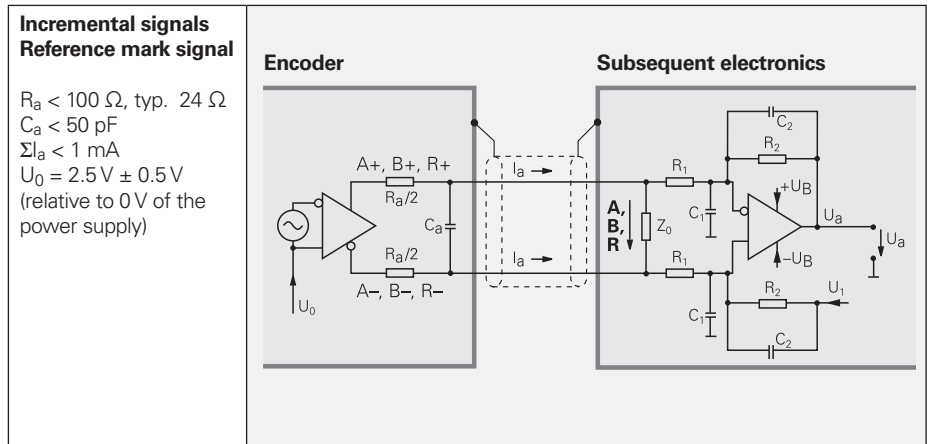

Gain 3.48

Monitoring of the incremental signals

The following thresholds are recommended for monitoring of the signal level M:

Lower threshold: 0.30 V_{PP}

Upper threshold: 1.35 V_{PP}

Interfaces

Incremental signals

HEIDENHAIN encoders with  interface incorporate electronics that digitize sinusoidal scanning signals with or without interpolation.

The **incremental signals** are transmitted as the square-wave pulse trains U_{a1} and U_{a2} , phase-shifted by 90° elec. The **reference mark signal** consists of one or more reference pulses U_{a0} , which are gated with the incremental signals. In addition, the integrated electronics produce their **inverted signals** $\overline{U_{a1}}$, $\overline{U_{a2}}$ and $\overline{U_{a0}}$ for noise-proof transmission. The illustrated sequence of output signals—with U_{a2} lagging U_{a1} —applies to the direction of motion shown in the dimension drawing.

The **fault-detection signal** $\overline{U_{aS}}$ indicates fault conditions such as breakage of the power line or failure of the light source. It can be used for such purposes as machine shut-off during automated production.

The distance between two successive edges of the incremental signals U_{a1} and U_{a2} through 1-fold, 2-fold or 4-fold evaluation is one **measuring step**.

The subsequent electronics must be designed to detect each edge of the square-wave pulse. The minimum **edge separation a** listed in the *Specifications* applies to the illustrated input circuitry with a cable length of 1 m, and refers to a measurement at the output of the differential line receiver. Propagation-time differences in cables additionally reduce the edge separation by 0.2 ns per meter of cable length. To prevent counting errors, design the subsequent electronics to process as little as 90 % of the resulting edge separation.

The max. permissible **shaft speed** or **traversing velocity** must never be exceeded.

The permissible **cable length** for transmission of the TTL square-wave signals to the subsequent electronics depends on the edge separation a . It is at most 100 m, or 50 m for the fault detection signal. This requires, however, that the power supply (see *Specifications*) be ensured at the encoder. The sensor lines can be used to measure the voltage at the encoder and, if required, correct it with an automatic control system (remote sense power supply).

Interface	Square-wave signals 
Incremental signals	2 square-wave signals U_{a1}, U_{a2} and their inverted signals $\overline{U_{a1}}$, $\overline{U_{a2}}$
Reference mark signal Pulse width Delay time	1 or more TTL square-wave pulses U_{a0} and their inverted pulses $\overline{U_{a0}}$ 90° elec. (other widths available on request) $ t_d \leq 50$ ns

Interfaces

Absolute position values

The EnDat interface is a digital, **bidirectional** interface for encoders. It is capable both of transmitting **position values** as well as transmitting or updating information stored in the encoder, or saving new information. Thanks to the **serial transmission method**, only **four signal lines** are required. The data is transmitted in **synchronism** with the clock signal from the subsequent electronics. The type of transmission (position values, parameters, diagnostics, etc.) is selected through mode commands that the subsequent electronics send to the encoder. Some functions are available only with EnDat 2.2 mode commands.

For more information, refer to the *EnDat* Technical Information sheet or visit www.endat.de.

Position values can be transmitted with or without additional information (e.g. position value 2, temperature sensors, diagnostics, limit position signals). Besides the position, additional data can be interrogated in the closed loop and functions can be performed with the EnDat 2.2 interface.

Parameters are saved in various memory areas, e.g.:

- Encoder-specific information
- Information of the OEM (e.g. "electronic ID label" of the motor)
- Operating parameters (datum shift, instruction, etc.)
- Operating status (alarm or warning messages)

Monitoring and diagnostic functions of the EnDat interface make a detailed inspection of the encoder possible.

- Error messages
- Warnings
- Online diagnostics based on valuation numbers (EnDat 2.2)

Incremental signals

EnDat encoders are available with or without incremental signals. EnDat 21 and EnDat 22 encoders feature a high internal resolution. An evaluation of the incremental signal is therefore unnecessary.

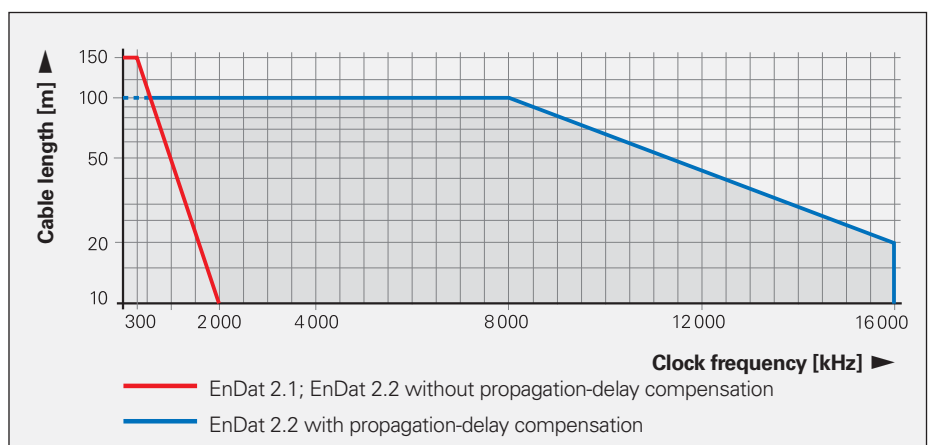

Clock frequency and cable length

The clock frequency is variable—depending on the cable length (max. 150 m)—between **100 kHz** and **2 MHz**. With propagation-delay compensation in the subsequent electronics, either clock frequencies **up to 16 MHz** are possible or cable lengths up to 100 m (for other values see *Specifications*).

Interface	EnDat serial bidirectional
Data transfer	Absolute position values, parameters and additional information
Data input	Differential line receiver according to EIA standard RS 485 for the signals $\overline{\text{CLOCK}}$, $\overline{\text{CLOCK}}$, DATA and $\overline{\text{DATA}}$
Data output	Differential line driver according to EIA standard RS 485 for the signals DATA and $\overline{\text{DATA}}$
Position values	Ascending during traverse in direction of arrow (see dimensions of the encoders)
Incremental signals	$\sim 1 V_{PP}$ (see <i>Incremental Signals 1 V_{PP}</i>) depending on the unit

General electrical information

Power supply

Connect HEIDENHAIN encoders only to subsequent electronics whose power supply is generated from PELV systems (**EN 50178**). In addition, overcurrent protection and overvoltage protection are required in safety-related applications.

If HEIDENHAIN encoders are to be operated in accordance with IEC 61010-1, power must be supplied from a secondary circuit with current or power limitation as per IEC 61010-1:2001, section 9.3 or IEC 60950-1:2005, section 2.5 or a Class 2 secondary circuit as specified in UL1310.

The encoders require a **stabilized DC voltage U_p** as power supply. The respective *Specifications* state the required power supply and the current consumption. The permissible ripple content of the DC voltage is:

- High frequency interference
 $U_{PP} < 250 \text{ mV}$ with $dU/dt > 5 \text{ V}/\mu\text{s}$
- Low frequency fundamental ripple
 $U_{PP} < 100 \text{ mV}$

The values apply as measured at the encoder, i.e., without cable influences. The voltage can be monitored and adjusted with the encoder's **sensor lines**. If a controllable power supply is not available, the voltage drop can be halved by switching the sensor lines parallel to the corresponding power lines.

Calculation of the **voltage drop**:

$$\Delta U = 2 \cdot 10^{-3} \cdot \frac{1.05 \cdot L_C \cdot I}{56 \cdot A_p}$$

where ΔU : Voltage drop in V

1.05: Length factor due to twisted wires

L_C : Cable length in m

I : Current consumption in mA

A_p : Cross section of power lines in mm^2

The voltage actually applied to the encoder is to be considered when **calculating the encoder's power requirement**. This voltage consists of the supply voltage U_p provided by the subsequent electronics minus the line drop in the power lines. For encoders with an expanded supply range, the voltage drop in the power lines must be calculated under consideration of the nonlinear current consumption (see next page).

If the voltage drop is known, all parameters for the encoder and subsequent electronics can be calculated, e.g. voltage at the encoder, current requirements and power consumption of the encoder, as well as the power to be provided by the subsequent electronics.

Switch-on/off behavior of the encoders

The output signals are valid no sooner than after switch-on time $t_{SOT} = 1.3 \text{ s}$ (2 s for PROFIBUS-DP) (see diagram). During time t_{SOT} they can have any levels up to 5.5 V (with HTL encoders up to U_{Pmax}). If an interpolation electronics unit is inserted between the encoder and the power supply, this unit's switch-on/off characteristics must also be considered. If the power supply is switched off, or when the supply voltage falls below U_{min} , the output signals are also invalid. During restart, the signal

level must remain below 1 V for the time t_{SOT} before power on. These data apply to the encoders listed in the catalog—customer-specific interfaces are not considered.

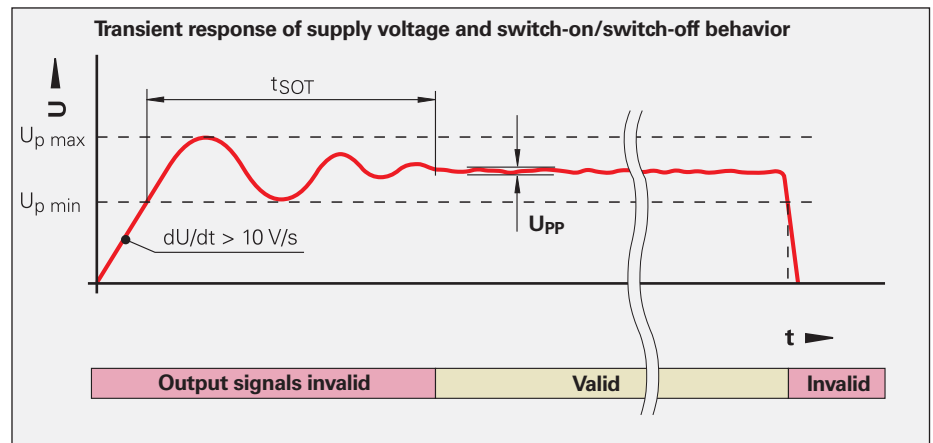

Encoders with new features and increased performance range may take longer to switch on (longer time t_{SOT}). If you are responsible for developing subsequent electronics, please contact HEIDENHAIN in good time.

Isolation

The encoder housings are isolated against internal circuits.

Rated surge voltage: 500 V

(preferred value as per VDE 0110 Part 1, overvoltage category II, contamination level 2)

Encoders with expanded supply voltage range

For encoders with expanded supply voltage range, the current consumption has a nonlinear relationship with the supply voltage. On the other hand, the power consumption follows a linear curve (see *Current and power consumption* diagram). The maximum power consumption at minimum and maximum supply voltage is listed in the **Specifications**. The maximum power consumption (worst case) accounts for:

- Recommended receiver circuit
- Cable length 1 m
- Age and temperature influences
- Proper use of the encoder with respect to clock frequency and cycle time

The typical current consumption at no load (only supply voltage is connected) for 5 V supply is specified.

The actual power consumption of the encoder and the required power output of the subsequent electronics are measured, while taking the voltage drop on the supply lines into consideration, in four steps:

Step 1: Resistance of the supply lines

The resistance values of the supply lines (adapter cable and encoder cable) can be calculated with the following formula:

$$R_L = 2 \cdot \frac{1.05 \cdot L_C}{56 \cdot A_P}$$

Step 2: Coefficients for calculation of the drop in line voltage

$$b = -R_L \cdot \frac{P_{E_{max}} - P_{E_{min}}}{U_{E_{max}} - U_{E_{min}}} - U_P$$

$$c = P_{E_{min}} \cdot R_L + \frac{P_{E_{max}} - P_{E_{min}}}{U_{E_{max}} - U_{E_{min}}} \cdot R_L \cdot (U_P - U_{E_{min}})$$

Step 3: Voltage drop based on the coefficients b and c

$$\Delta U = -0.5 \cdot (b + \sqrt{b^2 - 4 \cdot c})$$

Where:

$U_{E_{max}}$,

$U_{E_{min}}$: Minimum or maximum supply voltage of the encoder in V

$P_{E_{min}}$,

$P_{E_{max}}$: Maximum power consumption at minimum or maximum power supply, respectively, in W

U_P : Supply voltage of the subsequent electronics in V

Step 4: Parameters for subsequent electronics and the encoder

Voltage at encoder:

$$U_E = U_P - \Delta U$$

Current requirement of encoder:

$$I_E = \Delta U / R_L$$

Power consumption of encoder:

$$P_E = U_E \cdot I_E$$

Power output of subsequent electronics:

$$P_S = U_P \cdot I_E$$

R_L : Cable resistance (for both directions) in ohms

ΔU : Voltage drop in the cable in V

1.05: Length factor due to twisted wires

L_C : Cable length in m

A_P : Cross section of power lines in mm^2

Influence of cable length on the power output of the subsequent electronics (example representation)

Current and power consumption with respect to the supply voltage (example representation)

Electrically permissible speed/ traversing speed

The maximum permissible shaft speed or traversing velocity of an encoder is derived from

- the **mechanically** permissible shaft speed/traversing velocity (if listed in the *Specifications*) and
- the **electrically** permissible shaft speed/ traversing velocity.
For encoders with **sinusoidal output signals**, the electrically permissible shaft speed/traversing velocity is limited by the -3 dB/ -6 dB cutoff frequency or the permissible input frequency of the subsequent electronics.
For encoders with **square-wave signals**, the electrically permissible shaft speed/ traversing velocity is limited by
 - the maximum permissible scanning/ output frequency f_{\max} of the encoder, and
 - the minimum permissible edge separation a for the subsequent electronics.

For angle or rotary encoders

$$n_{\max} = \frac{f_{\max}}{z} \cdot 60 \cdot 10^3$$

For linear encoders

$$v_{\max} = f_{\max} \cdot SP \cdot 60 \cdot 10^{-3}$$

Where:

- n_{\max} : Elec. permissible speed in min^{-1}
- v_{\max} : Elec. permissible traversing velocity in m/min
- f_{\max} : Max. scanning/output frequency of encoder or input frequency of subsequent electronics in kHz
- z : Line count of the angle or rotary encoder per 360°
- SP : Signal period of the linear encoder in μm

Cables

For safety-related applications, use HEIDENHAIN cables and connectors.

Versions

The cables of almost all HEIDENHAIN encoders and all adapter and connecting cables are sheathed in **polyurethane (PUR cables)**. Many adapter cables for within motors and a few cables on encoders are sheathed in a **special elastomer (EPG)**. Many adapter cables within the motor consist of TPE wires (**special thermoplastic**) in braided sleeving. Individual encoders feature cable with a sleeve of **polyvinyl chloride (PVC)**. This cables are identified in the catalog as EPG, TPE or PVC.

Durability

PUR cables are resistant to oil and hydrolysis in accordance with **VDE 0472** (Part 803/test type B) and resistant to microbes in accordance with **VDE 0282** (Part 10). They are free of PVC and silicone and comply with UL safety directives. The **UL certification** "AWM STYLE 20963 80 °C 30 V E63216" is documented on the cable.

EPG cables are resistant to oil in accordance with **VDE 0472** (Part 803/test type B) and to hydrolysis in accordance with **VDE 0282** (Part 10). They are free of PVC, silicone and halogens. In comparison with PUR cables, they are only somewhat resistant to media, frequent flexing and continuous torsion.

PVC cables are oil resistant. The UL certification "AWM E64638 STYLE20789 105C VW-1SC NIKKO" is documented on the cable.

TPE wires with braided sleeving are oil resistant and highly flexible.

Temperature range

	Rigid configuration	Frequent flexing
PUR	-40 to 80 °C	-10 to 80 °C
EPG TPE	-40 to 120 °C	-
PVC	-20 to 90 °C	-10 to 90 °C

PUR cables with limited resistance to hydrolysis and microbes are rated for up to 100 °C. If needed, please ask for assistance from HEIDENHAIN Traunreut.

Lengths

The **cable lengths** listed in the *Specifications* apply only for HEIDENHAIN cables and the recommended input circuitry of subsequent electronics.

Cable	Bend radius R	
	Rigid configuration	Frequent flexing
Ø 3.7 mm	≥ 8 mm	≥ 40 mm
Ø 4.3 mm	≥ 10 mm	≥ 50 mm
Ø 4.5 mm EPG	≥ 18 mm	-
Ø 4.5 mm Ø 5.1 mm Ø 5.5 mm PVC	≥ 10 mm	≥ 50 mm

Ø 8 mm Ø 14 mm ¹⁾	≥ 40 mm ≥ 100 mm	≥ 100 mm ≥ 100 mm

¹⁾ Metal armor

Noise-free signal transmission

Electromagnetic compatibility/CE compliance

When properly installed, and when HEIDENHAIN connecting cables and cable assemblies are used, HEIDENHAIN encoders fulfill the requirements for electromagnetic compatibility according to 2004/108/EC with respect to the generic standards for:

- **Noise immunity EN 61000-6-2:**

Specifically:

- ESD EN 61 000-4-2
- Electromagnetic fields EN 61 000-4-3
- Burst EN 61 000-4-4
- Surge EN 61 000-4-5
- Conducted disturbances EN 61 000-4-6
- Power frequency magnetic fields EN 61 000-4-8
- Pulse magnetic fields EN 61 000-4-9

- **Interference EN 61000-6-4:**

Specifically:

- For industrial, scientific and medical equipment (ISM) EN 55 011
- For information technology equipment EN 55 022

Transmission of measuring signals—electrical noise immunity

Noise voltages arise mainly through capacitive or inductive transfer. Electrical noise can be introduced into the system over signal lines and input or output terminals.

Possible sources of noise include:

- Strong magnetic fields from transformers, brakes and electric motors
- Relays, contactors and solenoid valves
- High-frequency equipment, pulse devices, and stray magnetic fields from switch-mode power supplies
- AC power lines and supply lines to the above devices

Protection against electrical noise

The following measures must be taken to ensure disturbance-free operation:

- Use only original HEIDENHAIN cables. Consider the voltage drop on supply lines.
- Use connecting elements (such as connectors or terminal boxes) with metal housings. Only the signals and power supply of the connected encoder may be routed through these elements. Applications in which additional signals are sent through the connecting element require specific measures regarding electrical safety and EMC.

- Connect the housings of the encoder, connecting elements and subsequent electronics through the shield of the cable. Ensure that the shield has complete contact over the entire surface (360°). For encoders with more than one electrical connection, refer to the documentation for the respective product.
- For cables with multiple shields, the inner shields must be routed separately from the outer shield. Connect the inner shield to 0V of the subsequent electronics. Do not connect the inner shields with the outer shield, neither in the encoder nor in the cable.
- Connect the shield to protective ground as per the mounting instructions.
- Prevent contact of the shield (e.g. connector housing) with other metal surfaces. Pay attention to this when installing cables.
- Do not install signal cables in the direct vicinity of interference sources (inductive consumers such as contactors, motors, frequency inverters, solenoids, etc.).
 - Sufficient decoupling from interference-signal-conducting cables can usually be achieved by an air clearance of 100 mm or, when cables are in metal ducts, by a grounded partition.
 - A minimum spacing of 200 mm to inductors in switch-mode power supplies is required.
- If compensating currents are to be expected within the overall system, a separate equipotential bonding conductor must be provided. The shield does not have the function of an equipotential bonding conductor.
- Only provide power from PELV systems (**EN 50 178**) to position encoders. Provide high-frequency grounding with low impedance (**EN 60204-1 Chap. EMC**).
- For encoders with 11 μ App interface: For extension cables, use only HEIDENHAIN cable ID 244.955-01. Overall length: max. 30 m.

Minimum distance from sources of interference

HEIDENHAIN measuring equipment

The **PWT** is a simple adjusting aid for HEIDENHAIN incremental encoders. In a small LCD window the signals are shown as bar charts with reference to their tolerance limits.

	PWT 10	PWT 17	PWT 18

Accessories

EIB 1500

The EIB 1500 external interface box is an interpolation and digitizing unit for digital calculation of the positions of two scanning heads on rotational incremental HEIDENHAIN encoders. Absolute position values are available at the output once the reference marks are traversed. The high interpolation (with some encoders up to 16384-fold) also enables their use in speed control loops.
